HOW TO RAISE FLOWERS SUCCESSFULLY FROM SEED

Tender, or Greenhouse, means the plant will not stand the least frost. All such must be planted out late in spring (May) or in a greenhouse.

Half Hardy means the plant will stand any light frost, but needs protection against very cold weather. These should be planted out in the spring (March and April), not in the fall.

Hardy means the plant will stand considerable frost, or practically all we have on the Paeific Coast. These may be planted in the fall or in the spring (September to May). If sown in the fall they will come into bloom earlier than if sown in spring, even if the plants do not make much progress during the cold weather.

Annuals are plants that bloom the first year from seed, and the plant dies after one season. Tender annuals must be sown in spring (February to June), and most hardy annuals may be sown either in fall or spring (September to May).

Biennials are plants that bloom the second year from seed, and the plant dies after the second year. In California some of these will bloom the first year if sown early. Sow under the same conditions as perennials.

Perennials are plants that bloom the second year from seed, and the plant lives and blooms during successive years. If sown in early spring (February and March), many perennials will bloom the first year from seed. Perennials are best sown in the summer and early fall (May to September) for next year's flowers.

Cuitural Directions—It is better in most instances to start the seed in shallow boxes, about 3 inches in depth, using sandy soil with peat or leaf mold so that it will not bake. Set the boxes in a warm sheltered place, but protect from direct sunlight, as the seed is liable to be scorched up. When the plants have made the fourth leaf they should be pricked out, reset in another box and when well started they should be transplanted into the garden. When the seedlings are first set out, they should be shaded for a few days, and watered frequently.

Seeds of the hardier annuals may be sown where they are to grow, but, as a rule, it is preferable to transplant, as the plants are generally stronger and stand the drought better.

If the seed is to be sown directly in the garden, it should be done after the soil is well worked and fertilized. Sow thinly and always press the soil down firmly after sowing or else there is a danger of them drying up before the roots can get firm hold of the soil. After this has been done, cover with a very light coat of peat, sand or fine dry earth, the smallest seeds needing but a mere dusting to cover them. When up, the plants should be thinned sufficiently to prevent overcrowding. The removal of blossoms, as they commence to fade, is also essential, as otherwise the plants will soon cease bearing flowers.

The weeds should be kept down and the ground loosened often, so that the plants will receive the full benefit of the rains and dews, which they will not get if the ground is allowed to become hard and baked. Water often.

Lawn Grasses

LAWN GRASSES

To Make a Lawn—Spade deeply, adding commercial fertilizer, sheep manure or other organic fertilizers which contain no weed seeds. Rake to the desired grade and water thoroughly to settle the soil evenly. If this preparation is made two weeks in advance of sowing, the surface weed seeds will have germinated and may be removed. Now rake for the final grade and broadcast the seed at the rate of one pound to 150 square feet, except where other quantities are suggested in the grass seed

To prevent surface drying and crusting cover the seed with about 1/4 inch of moistened Imported Peat. Sprinkle carefully, using a fine spray to prevent washing. Water thoroughly, but avoid applying too much in one place to form puddles, which may float the seed and mulch into low spots. Sprinkle daily until seed is germinated, and when the grass has grown about one or two inches, pull all weeds and mow. To maintain a deep velvety green turf apply a good commercial fertilizer three or

four times a year.

For steep banks or slopes, burlap is sometimes used instead of mulch. It keeps the surface moist and prevents washing. Remove the burlap as soon as the seed germinates.

All of our grass seeds are the best grade. Please write for prices on larger quantities and quotations will be made promptly on the basis of the current market. Prices of grass seed fluctuate and quotations below are not guaranteed.

WE PAY POSTAGE anywhere within U.S. on items of grass seeds priced at 50c per pound or more. On other items refer to parcel post chart on inside front cover.

Spencer Sweet Peas are most satisfactory for spring and summer flowering, and may be planted from October to February.

The Early Spencer type is used for greenhouse culture, and will also bloom out of doors during the winter and early spring months in mild climates, from early fall sowings. Or they may be sown at any time during the spring or summer for flowering within a few months.

Sweet Pea seed sown during hot weather should be shaded with muslin or a mulch of loose straw or twigs, to keep the soil cool and prevent decay of the seed.

Culture—Dig a wide trench to a depth of 12 inches and after breaking up the bottom of trench fill in with several inches of peat or leaf mold to which add a liberal amount of bone meal; fill in the balance of the trench with good top soil. Tamp the soil down firmly and water thoroughly to the base. Let stand a few days until moderately moist. Never put the seed in too wet soil. Rake off the surface nice and smooth, make rows and plant seed about once inch deep, and two inches apart. Do not water until all the seed is up, at least half an inch out of the soil. (Nine-tenths of the failures are caused by watering too soon.). Thin out to at least six inches apart and train on wire netting or strings when plants are five or six inches high. Applications of complete chemical fertilizers during flowering period will add to the length of stem and size of blossoms. Keep well cultivated and water only as needed during the blooming period, as excessive moisture will cause the buds to drop.

Seasons to Sow Flower Seeds in Central California

(Reference to lower left column on inside front cover will assist in adapting this table to other sections as well)

This list enables one to tell at a glanee when the various flower seeds may be sown. As some perennials will bloom the same season if sown early in the year, we have stated the latest time in spring that they may be sown for this purpose. Several varieties of hardy annuals if sown in the fall will come into bloom earlier than if sown in the spring, even if the plants do not make much progress during the cold weather. Tender and half hardy annuals, if sown early, should be started in a warm, sheltered position and transplanted when the eold weather is over.

ARTICHOKE

Sow any time the weather is favorable, preferably in March or April. Soil should be a light, moist loam and seed should be sown thinly in drills 1 inch deep. Transplant when 6 inches high in rows 5 feet apart, and 4 feet between the plants. Save offsets from best plants for new supply as artichokes never come true from seed, some will prove inferior. When transplanting seedlings reject those with spiniest leaves.

WATERMELONS

The culture of watermelons differs from that of muskmelons mainly in that the hills should be wider apart, from 8 to 10 feet, according to the variety grown. An effort should be made to secure good strong vines early in the season, and this can best be done by taking care that the hills are large, mellow, and well drained, with the manure placed so that they will not dry out quickly under hot sun. Plant the seeds thickly when danger of frost is over and thin the plants to four of the strongest in each hill. All possible protection from insects should be given the young plants and their growth may be still further hastened by frequent application of liquid manure. They mature in 120 to 140 days. As a protection from insects, netting is frequently used. One ounce will plant about 25 hills.

MUSKMELON

A light, warm, rich soil is essential for this crop. When all danger from frost is over, plant the seed in slightly raised hills 4 feet apart each way, placing 6 to 8 seeds in each hill in a circle and covering with one inch of fine soil. Place a shovelful of old manure about 6 inches under each hill and tamp down firmly. Have the soil moist before planting so that no watering is required until the seeds have sprouted, otherwise they are apt to rot. After all danger of destruction by bugs is over, thin out to 3 plants to a hill; when about 1 foot long pinch off the tips to make them branch. This strengthens the growth of the vines and makes the fruit mature early. Muskmelons mature in 120 to 140 days. One ounce will plant about 50 hills.

Plant in well-manured hills, in the same manner as Cucumbers or Melons—the bush varieties 3 or 4 feet apart each way, and the running kinds from 6 to 8 feet. 8 to 10 seeds should be sown, 1 to 2 inches deep, in each hill, thinning out after they have attained their rough leaves and danger from bugs is over, leaving 3 or 4 of the strongest plants to a hill. The soil should be moist before planting so that no watering is required until the seeds have sprouted, otherwise they may fail to germinate. An occasional feeding of liquid manure will repay in size of fruits. One ounce of the summer varieties will plant about 25 hills and one ounce of the winter varieties about 15 hills. Summer sorts mature in 65 days and the winter sorts in 150 days.

TOMATO

For early plants sow in hotbeds early in March or April, in drills 5 inches apart and 1/4 inch deep; when the plants are about 2 inches high transplant into another hotbed 4 inches apart each way; plant out in the open ground early in May, or as soon as danger from frost is over, 4 feet apart each way in hills, which should have a shovelful of well-rotted manure mixed with the soil. Water freely at time of transplanting, but after the plants are well established water sparingly and at the roots only, as spraying the vines and overwatering causes the blossoms to drop off; when the first fruit is set, pinch off the ends of the branches to obtain early fruit. Sufficient plants for a small garden can be grown in a shallow box by placing it in a sunny window in a warm room. For late use sow in a sheltered border in May, and set out the plants in July; the green fruit may be picked off before frost and ripened under glass. GUARANTEE—The Hallawell Seed Company will exercise care to have all stock true to name; nevertheless, it is understood and agreed that should any stock prove untrue to name, the Hallawell Seed Company shall be liable only for the sum paid for the stock proving untrue, and shall not be liable for any greater amount.

PRICES quoted are f. o. b. San Francisco except where noted. Where express office differs from postoffice be sure to write each in the proper place on the order form.

CLAIMS—Should any errors occur we desire to be informed upon receipt of goods, that we may rectify them without delay. All claims must be filed within ten days after the arrival of shipment.

HALLAWELL'S SELECT ROSES

Hallawell's Select Roses are a selected No. 1 grade. They are grown under soil and climatic conditions suitable for production of vigorous bushes which will grow to strong sturdy plants. There are four commercial grades of roses and Hallawell's Select Roses are selected first grade. Bush Roses will bloom freely the first year, while climbing varieties often require two years or more to bloom profusely.

Bare root bush and climbing varieties are usually ready for delivery in December if weather conditions permit digging. They are available during January, February and March or until the bare root supply is exhausted.

PLANTING—Before planting dormant roses, remove the small branches and cut back the large ones to 5 or 6 inches, leaving an outside bud at the top. Plant to a depth where the bud-union will be just below the surface and pack the soil well around the roots, leaving no air spaces. Well-rotted manure and bone meal or other suitable fertilizer may be placed on the surface as a mulch after planting.

SPRAYING—To prevent and control mildew, spray with any good fungicide which will not discolor the foliage. A suggested solution is 3 teaspoons Bordelo and 3 teaspoons Acme Emo-Nik to 1 gallon of water. Acme Aphis Spray is also recommended for aphis control.

LATE SEASON PLANTING—Fine pot grown roses of many bush and climbing varieties are available during April, May, and June or until the supply is exhausted. These pot grown bushes are well established and growing, and will continue to grow in your garden without interruption. Prices are as listed, f. o. b. San Francisco. Shipment by express, transportation charges collect; shipping weight averages 5 to 6 pounds per bush.

Pruning

This should be done during the months of December, January and February; at that time the bushes are in a dormant condition. Cut just above a prominent but dormant bud that is pointing outward.

The Tea Varieties (T.) require to be more severely pruned than any other sort. Cut back to about 6 or 7 inches from the old wood each year; keep the center of the plant open and thin out all the weak wood, leaving about 5 or 6 shoots, according to the size of the plant.

Hybrid Teas (H. T.) should have almost as much pruning done as the Teas.

Hybrid Perpetuals (H. P.)—First cut out any dead or weak wood, keeping the center of the plant open, then cut the remaining shoots down to sound, healthy wood to within 6 or 12 inches of the base; this hard pruning keeps the plants compact and promotes new life for future years. After the first year they require little pruning except to cut out dead wood.

Austrian and Hybrid Briars (H. B.) require to be cut back fairly hard when planted out but afterwards need no pruning except to cut out dead wood.

Polyantha or Baby Roses (P.) should be but little pruned; merely cut out dead wood and keep the center of the plant from getting too crowded.

Single (S.) require little (if any) pruning when established, but will be the better for being cut back when planted.

Climbers. These are not usually pruned severely as their purpose is for mass effect. They should, however, be periodically thinned out.

Planting and Pruning—Planting may be done from December to March. Always dig large holes for the roots and add some old well-rotted manure. Deciduous fruit trees should be pruned back severely after planting, usually 2½ or 3 feet from the ground, leaving a few side branches where necessary, which are cut back to a few inches from the main stem. When the trees have been planted one year, cut back half the preceding summer's growth. Frequent cultivating is necessary.

BERRIES

Plant trellis varieties 6 to 8 feet apart each way. (Boysen 8 feet.) Provide a trellis 4 to 5 feet high. Vines may be left on the ground the first season and trellised any time after the canes are long enough. To make picking easy keep new growth cut off at the ground after the first season. When the crop is picked cut off all old wood, back to the ground, and later, train new growth on the trellis. In the spring, spray with a Dry Lime Sulphur solution. For best results, irrigate thoroughly at regular intervals (about once a week during fruiting season). Keep all berries well fertilized.
